gate electrode 16 is constructed by a metal layer or a polysilicon layer 20 and an underlayer, a gate oxide layer 18. In order to describe or ~~simulate~~apply the operation of the MOS on the computer to ~~simulate it's operation condition more easily~~, the structure of the MOS is represented by~~simplify~~ into circuit symbols. Fig. 1B is a circuit symbol ~~model~~ of a conventional NMOS transistor.

Figs. 1C and 1D are ~~character~~ diagrams showing characteristics of the NMOS transistor. Since the source and the substrate of the NMOS are usually grounded, ~~performance~~operation of the NMOS is controlled by the  $V_g$  and the  $V_d$ , wherein the  $V_g$  decides the switch state (on/off state) of the NMOS and the  $V_d$  decides the amount of the current passing through the drain, channel and source when the NMOS is opened. Therefore, as shown in Fig. 1C, the current  $I_d$  in the NMOS is almost zero when  $V_g$  is smaller than  $V_t$ . Simultaneously, when  $V_g$  is larger than  $V_t$ , the current  $I_d$  in the NMOS is proportionally increased with the  $V_g$ . As shown in Fig. 1D, under  $V_{g1}$ ,  $V_{g2}$  and  $V_{g3}$  (while  $V_{g1} < V_{g2} < V_{g3}$ ),  $I_d$  is directly proportional to  $V_d$  when  $V_d$  is relatively small. When the  $V_d$  is increased to reach a saturated drain voltage, the  $I_d$  is approaching~~losing~~ to an saturated situation.

~~Basing~~Based on the characteristics~~factors~~ provided by the ~~eharaeter~~ curves in Figs. 1C and 1D, various circuit characters of the NMOS shown in Fig. 1B can be simulated by the computer.

Page 6, the second paragraph to page 7, line 2.

Fig. 3 is schematic, view of a macro model of an NROM structure in a preferred embodiment according to the invention. As shown in Fig. 3, since the left-hand part of the NROM shown in Fig. 2 is a normal NMOS structure and the right-hand part of the NROM is an NMOS transistor with short channel length, high threshold voltage and serious DIBL effect because of the existence of charge trapped region 46, a normal MOS symbol element 50 in serial ~~series~~ with a short channel MOS symbol element 52 is used to represented the NROM structure described

Application No.: 09/815, 129

Docket No.: JCLA6683

above. It should be noticed that a MOS possesses the channel shorter than the channel of the MOS symbol element 50 is regarded as a short channel MOS. In Fig. 3 ~~identally~~, the normal MOS symbol element 50 comprising a first gate electrode 54, a first drain 56 and a first source 58 represents a MOS constructed by the drain 32, the source 34 and the left portion of the gate electrode 36 without the existence of charge trapped region 46. Moreover, the short channel MOS symbol element 52 comprising a second gate electrode 60, a second drain 64 and a second source 62 represents a MOS constructed by the drain 32, the source 34 and the other portion of the gate electrode 36 with the charge trapped region 46.

Furthermore, since the normal MOS symbol element 50 and the short channel MOS symbol element 52 share a common gate electrode as the gate electrode 36 shown in Fig. 2, the first gate electrode 54 is coupled with the second gate electrode 60. In addition, by comparing Fig. 2 to Fig. 3, since the first drain 56 is, indeed, the second source 62 so that the first drain 56 is in series coupled with the second source 62.

Page 8, last paragraph to page 9, line 8.

As shown in Fig. 5BA, when the NROM is operated under a reverse bias, charges are stored close to the source 34. The applied voltage  $V_D$  at drain will not affect the performance of the short channel MOS symbol element 90 unless the normal MOS symbol element 92 is "on" ~~so seriously as under forward reading operation because the negative charges are stored close to the source 34.~~ Clearly, both normal MOS symbol element 92 and short channel MOS symbol element 90 could affect the performance of the NROM. Therefore, only when a high voltage  $V_G$  is applied on the

gate electrode even though  $V_D$  is high (as represented by curve 82 in Fig. 5A,  $V_D=2.1V$ ), the normal MOS symbol element 92 and the short channel MOS symbol element 90 are turned on at the same time. ~~Therefore, the~~ to generate a larger  $I_D$  is relatively large. If the applied voltage  $V_D$  is as low as the applied voltage  $V_D$  ( $V_D=0.1V$ ) used in the forward bias operation mode, a relatively high  $V_G$  (as shown by curve 80 in Fig. 5A, larger than 2.1V) is necessary for inducing relatively large current  $I_D$ .
